Unusual method in tracheo-bronchial foreign body aspiration management

Ahmed Abdel-Aziz, Walid Abu Arab*

Abstract
Tracheo-bronchial foreign body aspiration could be a life-threatening condition that occurs mainly in children. Prompt diagnosis and intervention through foreign body retrieval are critical to prevent probable morbidity and mortality. The retrieval procedure could be difficult depending on the shape and consistency of the foreign body material. Surgeons can utilize special tools to help in the extraction of tracheo-bronchial foreign bodies. We present here a child patient who accidentally aspirated a plastic bead. He underwent successful retrieval of the foreign body using a Fogarty embolectomy catheter introduced through a rigid bronchoscope.

Keywords: Foreign body; aspiration; tracheo-bronchial foreign body

INTRODUCTION
Tracheo-bronchial foreign body aspiration could be a life-threatening event [1,2]. It occurs mainly in children [3]. Early diagnosis and management are important to avoid complications [1-3]. Endoscopic extraction could be difficult and may require the employment of special instruments [3]. We present here a child patient who accidentally aspirated a plastic bead. He underwent successful retrieval of the foreign body using a rigid bronchoscope and a Fogarty embolectomy catheter.

CASE REPORT
A nine-year-old male child was referred to the Cardiothoracic Surgery Department with a history of aspiration of a plastic bead into the trachea-bronchial tree. A previous trial of bronchoscopic extraction was done using a Dormia basket at another center. The child was asymptomatic. However, examination revealed decreased air entry over the left lung base. Plain chest x-ray showed a rounded smooth opacity related to the foreign body; it was located mostly in the left lower lobar bronchus (Figure 1). Routine laboratory investigations were performed. The findings were within the normal values for age and sex. Rigid bronchoscopy under general anesthesia was performed using the number 5 Karl Storz bronchoscope. A foreign body in the form of a white plastic bead with a central hole was visualized. Repeated attempts of extraction using conventional foreign body forceps were conducted with no

success.
A Fogarty embolectomy catheter was passed under vision through the central hole. The balloon was inflated. This was followed by the removal of the catheter holding the bead together with the bronchoscope as one unit (Figure 2).
Further examination of the tracheo-bronchial tree was conducted to exclude any traumatic injury or impacted secretions. No complications were encountered. The patient was discharged on the same day.

DISCUSSION

Foreign body aspiration occurs mainly in children [3]. Foreign bodies could be organic in nature, such as nuts and seeds, or inorganic like pins, nails, and dental appliances [4]. In this study, the child aspirated a bead, which is a rounded plastic piece with a smooth surface and a very small opening at its center. Usually, foreign bodies could be removed using extraction forceps [5]. However, sometimes, special tools need to be used such as a magnet for metallic objects [6] or a Fogarty catheter [7]. In the case at hand, the bead was rounded and smooth and impacted inside the lobar bronchus. It was difficult to grasp with forceps or to pass any tool like a Fogarty catheter between the bronchial wall and the bead. Surgery in the form of bronchotomy was an option. However, surgeons should exert their best efforts to avoid major procedures and the probable complications in such cases. Creativity and the ability to use available tools according to the type of the foreign body and its shape should be kept in mind. In our patient, a Fogarty catheter was used to pass through the central hole, followed by the inflation of its balloon. Then, the Fogarty catheter with its inflated balloon supporting the foreign body was removed with a rigid bronchoscope.
The procedure of foreign body extraction in infants and children requires the collaboration of the surgeon and the anesthetist. Both should be patient and communicate well to prevent intra-procedural complications.

CONCLUSION

In conclusion, the management of aspirated foreign bodies could be difficult. It necessitates the use of available instruments depending on the shape and structure of the foreign body in order to extract it endoscopically and avoid bronchotomy.
